ABSTRACT

The prevention of food loss throughout the supply chain, including manufacturers, has become a major challenge for a number of organisations. In addition, consumers are also increasingly interested in the authenticity of food and want to ensure that they receive the right quality of food. To address this issue, there is a need for reliable and robust tools to be available in the Industry 4.0 era that can trace the food throughout the supply chain from the farm through processing until it reaches the customer and, thus, ensure transparency. Using the people, process, and technology (PPT) model, this paper develops a blockchain-enabled food supply chain framework including the future opportunities and the present impediments based on the systematic literature review and semi-structured case interviews from the context of emerging economies. The study investigates the suitability of blockchain technology in resolving major challenges, such as traceability, trust, and accountability in the food industry. The study further paves the way for future researchers to address the technological and people-related challenges in the Industry 4.0 era to mitigate the emerging problems in the food sector. Interestingly, we did not find many issues in process- and performance-related aspects. The study offers empirical evidence of blockchain technology implementation in the Industry 4.0 era that opens up the discussion for future researchers and lists the potential threats.

Blockchain; Industry 4.0; food manufacturers; food supply chain; food security; track and tracing

1. Introduction

Food loss is often described as a ‘farm-to-fork’ damage problem (Aung and Chang 2014); it is defined as any food substance, liquid or solid, cooked or uncooked, that is thrown away or discarded including food processors. Food loss is a global challenge in the developing and the developed countries (de Lange and Nahman 2015). The United Nations Food and Agriculture Organisation (FAO) estimates that around 40 percent of the food produced is lost or wasted throughout the entire food chain (Warker 2018). This percentage is even higher in developing countries. Food travels through what is often a vast network of farmers, retailers, distributors, transporters, storage facilities, processors, and suppliers before reaching the end consumer and has to undergo processes such as post-production, harvesting, processing (warehouses, packaging), transportation, distribution, and sales. Yet in almost every case, this journey remains an unseen dimension of purchased food products (Ahlmann 2018). In a food supply chain, loss can be classified into five categories: agricultural loss, postharvest loss, processing loss, distribution loss, and consumption loss (Kummu et al. 2012). Most food loss occurs throughout the food system starting at farms and ending at households during post-harvest including

processing (warehouses, packaging), transportation and distribution, availability in the supermarkets, and purchase by the consumers. Food loss in developing countries is much more prevalent in the early and the middle stages of the supply chain, and it is primarily related to the inadequate supply chain and logistics infrastructure and management, low levels of technology use, and low investment in the food production systems. In contrast, in developed countries, a significant amount of food is wasted during the marketing and consumption stages (Warker 2018).

The increasing globalisation of food production and trade has opened up the access to food and led to an increase in consumer options (Fox et al. 2018). This not only makes the supply chain longer and more complex, but it also adds significant tracking and safety challenges, which necessitates change to the farm-to-fork business models (King et al. 2017). In addition, the intrusion of counterfeit products is affecting both the integrity of brands and the wellbeing of consumers (Chang, Iakovou, and Shi 2020). The food supply chain is facing uncertainties because of product perishability. In addition, ‘information asymmetry’ between the stakeholders is one of the major factors that lead to food fraud (Mao et al. 2018b; Galvez, Mejuto, and Simal-Gandara 2018). Thus,

there is a need for information sharing due to pilferage, inefficient transactions, etc. that lead to a lack of trust among the supply chain partners. In the agri-food sector, traceability of food is becoming a major differentiator and so is imperative for organisations (Saber et al. 2019). Thus, it is important to have a centralised and effective traceability system that ensures information connectivity among all the partners (Galvez, Mejuto, and Simal-Gandara 2018; Fatorachian and Kazemi 2018).

The food tracking system enables the supply chain to measure the level of safety of perishable food products, tracing the journey from where they are grown, handled, or stored and under what conditions they are transported or processed, thus leading to the development of a transparent and authentic chain of records of the food ecosystem (Godsiff 2016). In the food industry, the provenance and traceability of information helps to improve the quality as well as the safety of food (Saber et al. 2019). In addition, the evolution of technologies in the era of Industry 4.0 has the potential to prevent unnecessary waste and reduce the economic burden of product recalls, outbreaks, cross contamination, etc. Advanced technologies, including the Internet of Things (IoT) and blockchain, have been considered in many industries to increase traceability, but in the food industry, little progress has been made, particularly as regards creating more secure food-supply chains. However, other than the above reported issues, many unknown impediments related to people, process, technology, and performance can creep into the food supply chain and so need further investigation.

While blockchain technology is relatively a new technology, interest in using the technology in companies and the development of use cases is growing exponentially (Bumblauskas et al. 2020). In this process, blockchain technology can provide a way to achieve the immutable storage of data that can reduce the need for third party verifications (Lin and Liao 2017). Non-involvement of third party engagement will be helpful for businesses and consumers in the contemporary complex supply chains in the era of Industry 4.0 (Perboli, Musso, and Rosano 2018). In particular, this technology has a greater viability in the food industry, as it can help to reduce the food loss along global supply chain stages, monitor temperature variation during the transport, increase transparency of food processes, and so on. Besides traceability, the implementation of blockchain technology can help to reduce labour costs (Kshetri 2018) and other operational costs when lean and automated processes are in practice (Dobrovnik et al. 2018).

To date, there has been very little research on blockchain technology, and thus, it is difficult for organisations to understand how the blockchain technology can be implemented in Industry 4.0 (Galvez, Mejuto, and Simal-Gandara 2018). The literature and empirical evidence of blockchain implementation issues in supply chain management is extremely scarce (Queiroz, Telles, and Bonilla 2019; Calatayud, Mangan, and Christopher 2019; Chang, Iakovou, and Shi 2020). However, as blockchain technology offers significant advantages in the era of Industry 4.0, there is a need for research on how its implementation can help businesses create value

(Treiblmaier 2018; Dobrovnik et al. 2018; Bumblauskas et al. 2020). There are several ongoing pilot studies globally, so it is not obvious what are the typical issues that prevent the implementation of this technology and to what extent it is adaptable to the context of emerging economies typically in the context of the food supply chain. Hence, from the research perspective, this paper explores the opportunities for and impediments to using blockchain technology in a food supply chain.

Briefly, this study investigates some of the following pragmatic open questions:

1. What are the opportunities for and impediments to implementing blockchain technology in the era of Industry 4.0 food supply chains?
2. What are the specific implementation issues in terms of people, processes, technology, and performance perspectives?

In particular, we have used the people, process, and technology (PPT) model to address the objectives of this research study (Prodan, Prodan, and Purcarea 2015). PPT is considered the viable model for transforming and managing an organisation. In accordance with this framework, people-related strategies and processes evolve with the emergence of technology. The proper balance of PPT along with performance will enable firms to be successful. The PPT model has been applied in a number of disciplines although it is widely popular in the information technology management discipline amongst others. Hence, the PPT model is a viable framework for understanding the research challenges in blockchain implementation in supply chains.

Primarily, the major contribution of this study is to develop a blockchain-enabled food supply chain framework that classifies the opportunities and impediments in accordance with process, people, technology, and performance categories. We used the combination of systematic literature review (SLR) and semi-structured interviews to achieve the above stated objectives. The SLR helped us to know about the opportunities for and impediments to the use of blockchains in the food supply chain from an overall perspective, while semi-structured interviews helped us to know the perspective of professionals specifically from the Turkish and Indian food supply chains stakeholders.

The rest of the paper is organised as follows. Section 2 reviews the literature on food supply chain challenges, blockchain technology, and the potential use of blockchain technology in the food supply chain. Section 3 presents the research methodology adopted to achieve the desired objectives of this study. The results are presented in Section 4, and finally, conclusions and limitations are discussed in Section 5.

2. Literature review

2.1. Food supply chain challenges

Food quality and safety is becoming increasingly important, and failure to implement rigorous monitoring and

traceability processes can lead to illness and severe reputational damage to an organisation (Aung and Chang 2014). Recently, several food chains have been subjected to safety scandals, such as the horsemeat scandal, the peanut butter salmonella outbreak, etc. (Crossey 2017). If consumers cannot be certain that the food they are eating is safe and has been authentically sourced, they are likely to shop elsewhere, which can have a profound impact on a business's bottom line.

Maintaining food safety and providing the customer with the right quality food is a significant challenge. The major difference between a food supply chain and the other supply chains is the change in quality of the food material between the point of origin and the point of consumption (Apaiah et al. 2005). Thus, food products need to be traced throughout the supply chain to ensure that issues regarding the right quality, origin information, and transparency- and tracing-related issues are managed.

Indeed, the major issues that need to be managed to ensure traceability in a food supply chain can be sub-categorised as technical, managerial, and environmental (Aung and Chang 2014). The greatest challenge with the traceability of food is the exchange of information in a standardised format, precisely and effectively, to all the stakeholders involved in the supply chain (Moe 1998; Aung and Chang 2014). Paper-based systems are widely used in many small and large organisations to promote traceability, since digital systems are expensive, and operating and maintaining them requires extensive investment in resources (Karippacheril, Rios, and Srivastava 2017). However, paper-based systems have a number of limitations. Another barrier to food traceability is the associated costs in implementing traceability systems, especially for small scale producers specifically in developing economies (Kelepouris, Pramataris, and Doukidis 2007; Aung and Chang 2014). The high administrative costs also add significantly to the cost of technology. Finally, standardisation is difficult because of the different features of the members involved in the supply chain (Wognum et al. 2011). Thus, there is a need for cost effective systems that can provide accurate, up-to-date, and reliable information in a standardised format to all the stakeholders involved in the food supply chain (Opara 2003).

2.2. Industry 4.0 and technological adoption in food supply chain

The recent review by Ben-Daya, Hassini, and Bahroun (2019) indicated the availability of conceptual models for IoT applications in the food and manufacturing industries and the scarcity of analytical and empirical studies. The food traceability systems require the identification of entities and locations to follow the journey of food in the supply chain in the era of Industry 4.0. Data-capture technologies include radio frequency identification (RFID), barcodes, wireless sensor network (WSN), alphanumeric codes, etc. RFID has been found to be the most advanced technology for food traceability (Aung and Chang 2014), and has been applied by a number of organisations. Regattieri, Gamberi, and Manzini (2007)

proposed a system that uses the combination of alphanumeric code and RFID to trace cheese products and that also allows the customers to trace the product they have purchased. Similarly, Shanahan et al. (2009) presented a framework to trace beef from farm to slaughter, based on RFID technology. For internal traceability and chain traceability of a grain supply chain, Thakur and Donnelly (2010) recommended a generalised framework that uses a relational database management system and XML. In addition, Ruiz-Garcia, Steinberger, and Rothmund (2010) suggested a model that uses web-based systems for tracking batch products throughout the food supply chain. However, RFID systems have certain disadvantages; for example, the cost of the tags used in RFID systems is high (Aarnisalo et al. 2007). Moreover, it is difficult to achieve 100% readability of RFID tags through metal, glass, and liquid (Petersen 2004). Thus, there is a need for systems that are cost-effective, are compatible with the existing technology, can serve the required purpose, and most importantly, can be adopted by all organisations.

2.3. Blockchain review

A blockchain is a reliable and unalterable digital data ledger for monitoring the transactions through the distributed consensus process (Kamble, Gunasekaran, and Arha 2019; Galvez, Mejuto, and Simal-Gandara 2018). As a new business collaboration tool, blockchain technology supports a secure, shared data network and allows untrusted parties to reach a consensus on a shared digital history, without using a trusted intermediary (Swan 2015; Calatayud, Mangan, and Christopher 2019). A blockchain does not need any centralised authority and eliminates intermediaries in the process, allowing for faster, safer, and more efficient communication and operations between two parties (Pilkington 2016). Furthermore, smart contracts, also known as programmable protocols, are used in a blockchain to enable parties to agree on certain conditions. This also allows the sensitive data on the blockchain to be stored in the database encrypted with hash algorithms, so that the data can be protected securely (Ahlmann 2018). A blockchain enables the visibility of contracts across members in the supply network including agreements and regulatory check-points (Marques, Martins, and Araújo 2020). As mentioned earlier, a blockchain's inherent immutable characteristic supports the authenticity of information (Dolgui et al. 2020). Blockchain technology is at the early stage of development (Kshetri 2017; Calatayud, Mangan, and Christopher 2019); however, it has made substantial progress in the last five years. Everledger is using blockchain technology to transfer their diamonds in a trusted and credible way. For example, if we see a tag such as 'Everledger satisfied', then our mobile phone is able to scan the IoT chip for the diamond's history and transactions.

The blockchain technology was first conceptualised in 2008 in the financial sector, where it was known as a peer-to-peer electronic cash system (Nakamoto 2008). Initially, it was used as the foundation of a fully distributed crypto-currency unit (bitcoin), but it has gradually expanded into other

sectors, such as the healthcare, insurance, and agriculture industries and e-commerce to improve full transparency and accountability (Subramanian, Chaudhuri, and Kayikci 2020). Blockchain technology is primarily recognised for secured crypto money transactions (Crosby et al. 2016), and potentially, its applications in other sectors can deal with asset ownership, acceleration of transaction time, cost reduction, and reduced risk of fraud. Blockchain technology is also being integrated by a number of manufacturing companies (Xu, Xu, and Li 2018). Thus, blockchain technology has the potential to be applied in multiple industries and to initiate organisational change (Viswanadham 2018).

Blockchain technology stores and shares information across a network of users in an open virtual space, and it allows users to view all the transactions simultaneously and in real-time (Wang, Han, and Beynon-Davies 2019). Each block contains the data of all the transactions in the system within a period of time, and it creates a digital footprint which can be used to verify the validity of the information and connect with the next block (Beck et al. 2016). There can be a huge number of such blocks in the blockchain, and the blocks are linked to each other (like a chain) in a proper linear, chronological order with every block containing a hash of the previous block. The changes to the information that is stored in the ledger needs approval by consensus from each node of the network (Calatayud, Mangan, and Christopher 2019). This is possible because in a blockchain, the data infrastructure is visible to all the entities, and no single entity controls the data (Niranjanamurthy, Nithya, and Jagannatha 2019; Wang, Han, and Beynon-Davies 2019). Thus, a blockchain provides better visibility in procurement, accurate and reliable data for analytics, and increased trust among all participants in a supply chain network. Blockchain technology also helps to reduce the human interaction in non-value-added activities (Bibby and Dehe 2018). A selection of smart contracts can be included in the blockchain platform to facilitate secure communication between the users and machines (Ndraha et al. 2018).

Blockchain technology integrated with other artificial intelligence (AI) technologies can potentially mitigate issues surrounding trust, traceability, and collaboration in a supply chain. The cryptocurrency technology is also used by different applications, such as VeChain, for certification Waltonchain for apparel supply chains, Ambrosus for food and medicine supply chains, and Modum exclusively for pharma supply chains. VeChain has one of the most impressive partnership lists in the crypto industry. The network has partnered with DNV GL for certification, PWC for audit and advisory, Kuehne and Nagel for supply chain and logistics, the Chinese tobacco industry, and BitOcean & Fanghuwang for financial services. VeChain was launched in FY16 with functional smart contracts.

2.4. Blockchains in the food supply chain

Several of the issues discussed in the previous sections relate to improving collaboration and visibility in inventory and logistics to react promptly to disruptive events (Chang,

lakovou, and Shi 2020). Blockchain technology can help to improve the management and transparency of food supply chains (Tse et al. 2017; Ahlmann 2018) by helping to trace the inventory of products throughout the supply chain (Pournader et al. 2020). However, monitoring the food supply chain and controlling food loss with blockchain technology is challenging. Indeed, the Global Food Traceability Centre has identified several challenges to the implementation of food traceability systems. These include a rapid shift in the preferences of customers, demands from regulators that are conflicting and overlapping, the variation of traceability by product and by industry, the lack of records, and weak technical systems that prevent rapid response times (Galvez, Mejuto, and Simal-Gandara 2018).

There are currently only a few blockchain-based pilot applications in the food industry. The first pilot application to trace food using a blockchain was carried out by a start-up called Provenance (Tripoli and Schmidhuber 2018; Saberi et al. 2019). Yellowfin and skipjack tuna fish were tracked throughout the entire supply chain, from fishermen to distributors and retailers, and from shore to plate. The digital record was held on the blockchain, accessible to anyone with the unique identifier attached to the item such as a QR code or RFID tag or using any other hardware technology, so that the end users could track the whole journey of their tuna fish sandwiches on a smartphone and get information about producers, suppliers, and all the relevant procedures. In another pilot study, 10 major food suppliers including Walmart, Nestle, and Unilever, in collaboration with IBM built a consortium to apply blockchain technology to the food supply chain to improve food safety and transparency and to detect sources of contamination quickly (Barnard 2017). Tian (2017) proposed a food traceability system based on the blockchain technology and IoT, which will deliver real time safety status of food products to supply chain partners. The proposed method provides the benefits of tracking and identifying fake products.

Maersk and IBM have started a venture to establish a global blockchain-based system for digitising the trade work-flows and end-to-end shipment tracking (Allison 2017; DHL 2018). Their blockchain concept has been tested using shipments of flowers to Royal Flora Holland from Kenya, and mandarin oranges from California and pineapples from Colombia into the Port of Rotterdam. Another 'food chain' prototype was developed by Deloitte (2017a), which is capable of tracking all the ingredients in a particular product along the length of the supply chain. Such technology could potentially allow a consumer in China to pick up a product, scan an RFID tag on a mobile app, and be able to see where each ingredient in that product came from. In addition, Carrefour launched a food blockchain solution in early 2018 to track its quality line products. It was tested with the network of livestock farmers for chicken products from the hatchery for incubation to farm, slaughter, and processing and distribution, where a form of a simple QR code on the chicken's packaging is used. Subsequently, the solution was deployed for four other products: tomatoes, eggs, milk and Rocamadour cheese (Carrefour 2018). Furthermore, Albert

Heijn, Holland's largest supermarket chain, has revealed a new blockchain system in partnership with its supplier, Refresco, to make the production chain of orange juice transparent. Thus, the customers can collect the maximum amount of information about the source of Albert Heijn's own-brand 'sustainable' product. The end-to-end route of its production, from Brazil to the Netherlands, can be traced through scanning a QR code on the orange juice carton (Huillet 2018). The benefits of blockchain technology include the ability to monitor the operation's progress in real time, provide data verification, reduce the risk of fraud, and shorten the cash cycle. Apart from transparency and traceability, blockchain technology also brings economic benefits in terms of facilitating faster transactions to pay farmers more quickly. It also prevents price coercion and retroactive payments in the food industry. Louis Dreyfus Company sold 60,000 tons of American soybeans to the Chinese governments by using blockchain-driven agriculture commodity trade, which demonstrated significant efficiency improvements for all participants in the chain. The entire transaction took only a week by reducing the total logistics time by 80% (LDC 2018).

A blockchain can be used in the food sector so that each and every party along the length of the supply chain (producers, processors, and distributors) can provide traceability information about their particular role and for each batch of

the product (dates, places, farm buildings, distribution channels, potential treatments etc.). For the goods to be traceable from farm to fork, all the parties of the food supply chain that handle the goods should be linked to the blockchain and collaborate on a blockchain consortium to share all the food-related data, such as Hazard Analysis and Critical Control Point (HACCP) records, quality records, temperature records, humidity records, verification records, tracked food information, and so on. Each step is recorded in the blockchain to reduce the potential hazards in terms of spoilage (temperature, humidity, expiry), contamination (toxins, insect, bacteria, viruses) and compromise (tampering, misrepresentation, substitution). Figure 1 shows the blockchain in the dairy sector, where large commercial dairy companies face the challenge of tracking the provenance of their milk, as they often source from multiple milk producers (Deloitte 2017). Further, the IoT could potentially play a role here. Internet-connected equipment, such as trucks and storage coolers, could monitor which objects they are housing and tag those objects with the relevant environmental conditions, such as temperature, humidity, light, shock, or location, and thus provide assurance that a product is safely handled through the entirety of its journey. Blockchain technology can help to inform the customer of the way it reached to them, especially for costly and sensitive items. For example, a medicine package might include a microchip sensor (IoT chip) that records every environment from the departure from manufacturing unit until it reaches at consumer's hand. Moreover, the data have to be regularly updated on a shared and censorship-resistant blockchain ledger. This could be verified using a phone if the medicine were not available in the required environment. With the merger of IoT with a smarter ledger, i.e. the blockchain can verify the sensitive product rather than trusting the seller.

The stakeholders involved in the food supply chain from farm to fork are shown in Figure 2, which includes farmers; distributors; packers; processors; wholesalers; retailers; and

Figure 1. Blockchain in the Dairy Sector.

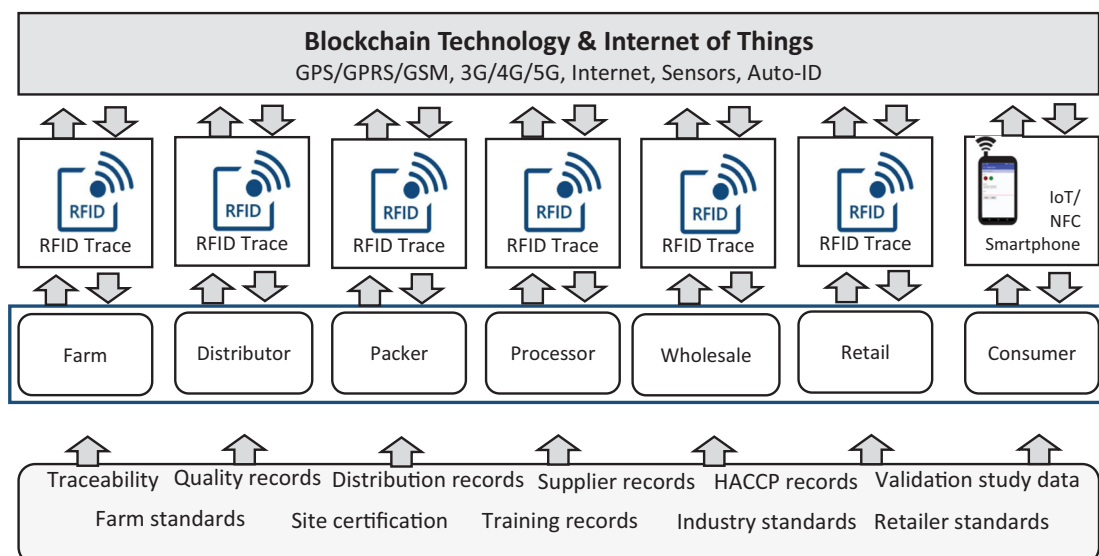

Figure 2. Blockchain-driven cold food supply chain.

customers, such as grocers, restaurants, traders, and end users, who jointly act and share food-related data using a blockchain consortium. The blockchain is the core of the solution, but on its own, it is not enough; it should be used with IoT devices, Auto-ID (RFID/NFC technology), GPS, GPRS, 5 G, wireless sensor networks, and other digital applications. The joint responsibility and transparency benefits food security with low transaction costs and instantaneous application. The blockchain assigns unique digital identifiers (event-specific data) to food products including growth conditions, product ID, lot/batch/serial numbers, and expiration dates. Tracing a food journey can help prevent food waste and instigate end consumers to calculate the ecological footprint of the food they consume as well as rerouting the surplus food to regions that need it. In addition, the blockchain's shared register of food would enable supply chain members to identify the source of foodborne illnesses and reduce food fraud. A combination of blockchain and IoT sensors data would automate decisions made by supply-chain members including farmers, processors, distributors, and retailers through smart contracts to address food safety issues, identify and implement solutions for recurring problems, and proactively identify and remove products in the case of foodborne illnesses or recalls that are at an elevated risk of contamination based on the handling history. This means that manufacturers and retailers have the potential to eliminate products at risk before they even reach the consumer, thus reducing the issues that come from issuing a recall including cost, consumer safety, damaged brand reputations, and decreased customer loyalty.

As digital technologies are increasingly used to manage farms, blockchain technology will promote the sharing of on-farm data. In short, blockchain-based food tracking can ensure the following (ChainLink 2018):

- provenance: stronger assurance of origin and chain-of-custody
- recalls: faster and more precise recalls
- freshness: fresher produce and meat, reduce waste and spoilage
- safety: fewer contamination incidents

The development of blockchain applications also empowers the entire chain to be more responsive to any food-safety disasters, such as the horsemeat scandal and peanut butter salmonella outbreak in the agri-food industry, as mentioned earlier, and it prevents food fraud (Crossey 2017). Blockchain technology thus offers immense potential for food safety and verification in the agri-food industry. In the food supply chain, for example, a retailer would know with whom his/her supplier had been dealing. Additionally, since transactions are not stored in any single location, it is almost impossible to hack the information. For consumers, by reading a simple QR code with an NFC-integrated smartphone (Crossey 2017), data such as an animal's birth, use of antibiotics, vaccinations, and location where the livestock was harvested, can easily be conveyed to the consumers.

Conceptual and pilot studies have illustrated that there is a huge potential to scale up the technology to the food sector; however, at implementation level, it is very difficult to identify what are the drivers and barriers in integrating the use of blockchain technology in the food sector from the managerial perspectives, such as people, process, performance, and technology.

3. Methodology

The methodology of this research is based on a systematic literature review (SLR) and case interviews with the focussed group of experts/stakeholders from the food industry.

3.1. Systematic literature review

A research strategy for SLR was adopted as per the three stages, such as 'planning the review', 'conducting the review' and 'reporting and dissemination', offered in Tranfield, Denyer, and Smart (2003) in order to review the most relevant literature. The three SLR stages are reported in the following sections.

(i) Planning the review:

Research scope: In this stage, the need for the review was identified to understand which studies have been published in the field of 'food and blockchain' between 2008 to 2020. The first paper on blockchains was published in the year 2008; hence, we made 2008 a reference year.

Search process: A comprehensive search process was conducted to classify all the primarily available published and catalogued research articles relevant to the research topic of interest. The list of synonyms, abbreviations, and alternative words of the major terms are reported.

The keywords and their synonyms were based on the existing literature in the domain of blockchain and food supply chains. The major keywords and their synonyms were concatenated with the help of 'OR' and 'AND' operators to construct the search strings that were used for the identification of relevant primary studies.

Inclusion and exclusion criteria: To the best of our knowledge, all published studies in journals, conferences, symposiums, and books related to blockchain technology and its applications, and to the service management and event management process in the food industry were included in the study. Considering the early stage, the study also included workshops, white papers, experience/business/technical reports, presentations, and bulletins. Research studies that did not explicitly discuss food in the context of blockchain technology and IoT were excluded. We also excluded master and PhD dissertations that were not published in journals or conferences. Furthermore, all informal literature surveys were excluded. Duplicated articles were not considered. Additionally, those articles that were reported in languages other than English were also excluded.

(ii) Conducting the review:

Identification of research. Primary articles were selected according to the above-listed search string with the following combination of keywords and inclusion of the study in one of the global databases listed below after the keywords.

Search string, which was prepared for keywords search used for the study, is as follows: 'blockchain' OR 'blockchain technology' AND 'food' AND 'supply chain' OR 'logistics' AND ['food industry' OR 'agrifood' OR 'agri-food' OR 'agriculture' OR 'food supply' OR 'food supply chain' OR 'food ecosystem' OR 'blockchain ecosystem' OR 'food safety' OR 'food security' OR 'food waste' OR 'traceability' OR 'transparency' OR 'ERP' OR 'enterprise resource planning' OR 'internet of things' OR 'IoT' OR 'blockchain of food' OR 'food processor' OR 'supply chain collaboration' OR 'food Blockchain' OR 'food blockchain participants' OR 'food fraud' OR 'food scandal' OR 'food recalls' OR 'standards' OR 'architecture' OR 'smart contracts'].

The following thirteen integrated digital databases that cover heterogeneous disciplines were used to collect the research articles, conference papers, books, and book chapters: ABI/Inform Complete/ProQuest, IEEE Xplore, ACM Digital Library, EBSCO, Springer Link, Wiley, Taylor & Francis, Jstor, Science Direct, Web of Science, Scopus, Google Scholar, and Research Gate. Furthermore, search engines and portals were used to find information on 'food' and 'blockchain' in white papers, workshop papers, reports, and presentations for the study: www.google.com, www.bing.com, www.yahoo.com, www.ask.com, www.yandex.com, www.linkedin.com, www.theconversation.com, www.forbes.com, www.theguardian.com, www.ibm.com/blogs/blockchain/, www.newfoodmagazine.com, www.globalfoodblockchain.org, www.agroconnect.nl, www.foodsafetynews.com, and www.economist.com. In addition, some webpages were searched in order to collect information on the recent developments of blockchain startups in the food industry: Arc-Net (www.arc-net.io), Filament (www.filament.com), SkuChain (www.skuchain.com), FarmShare (www.farmshare.us), Agridigital (www.agridigital.io), Origen Trail (www.origin-trail.com), Agriledger (www.agriledger.com), Farm2Kitchen (www.farm2kitchen.com), Provenance.org (www.provenance.org), Chainvine (www.chainvine.com).

Selection of studies: Here, a tollgate approach with five phases in accordance with Khan et al. (2017) was used to narrow down and to select the most relevant primary studies as shown in Figure 3. The details of the five phases are explained. In Phase 1, the search was carried out using keywords or strings, which resulted in 173 articles. In Phase 2, scanning of titles and abstracts using inclusion/exclusion criteria made it possible to remove duplicate articles thereby reducing the sample to 152 articles. In phase 3, the introduction and conclusion sections of 152 articles were evaluated using inclusion/exclusion criteria, which made it possible to remove an additional 12 articles thereby reducing the sample size to 140 articles. Next, in phase 4, filtering was done by reading the full text as per the inclusion/exclusion criteria, which resulted in a reduced sample of 129 articles. Finally, in phase 5, articles were selected based on primary studies, which resulted in 125 articles identified for further analysis.

Data Extraction: Overall, the literature search using the above tollgate approach resulted in 125 relevant papers. The primary studies considered are listed alphabetically in Table 1. Each paper was read thoroughly by one of the authors to identify the opportunities and impediments of blockchain technology in the food industry. In addition, each paper was categorised according to the PPT aspect, and one more author in the team verified these independently.

Data Synthesis: The analysis of the selected primary studies revealed that the most relevant opportunities to use blockchain technology in the food sector include maintain transparency throughout the food supply chain, accurately track goods, maintain a permanent ledger, reduce costs, decentralise infrastructure, improve efficiency, reduce fraud, enhance security, scale the ecosystem, automate, and innovate. However, in tandem with opportunities, there are several impediments to using this technology. These include complexity of the technology; regulatory implications, such as market regulations; level of trust; implementation challenges; competing platforms; standardisation related to data standards and semantics; scalability in terms of performing with very large numbers of transactions; immutability, etc. For example, if data can be updated, then immutability is lost, i.e. if data cannot be updated then how is it possible to deal with changes in the real world; for example, transaction speed, such as throughput; transparency, such as transparency in data with stakeholders to maintain business confidentiality; level of transparency; digitalisation; training; awareness; and too many choices limit the use of this technology.

(iii) Reporting and dissemination:

The selected articles are reported according to publication year, type of article, and as per PPT model classification category, as shown in Figures 4–6 respectively. Blockchain research in the food field has been attracting interest from researchers as the number of publications is growing yearly, and almost 58% of the selected papers are research articles. Most of the papers studied the technology aspect of blockchains, 53% of papers are technology-oriented papers, 31% focus on process, and 16% focus on people. Based on this review, it is understood that blockchain technology could improve the traceability of shipments by providing better access to information and allowing food providers to identify the precise point of any contamination before it causes further loss in revenue or results in waste products. Thus, food security leads to low transaction costs and instantaneous application. Attaching unique digital identifiers to food products would make them traceable throughout the supply chains, such as origin of products, growth conditions, batch numbers, the factory they come from, processing methods, expiration dates, temperature during storage, and even the distribution details. The in-depth review of selected articles according to the PPT aspect with the limitations/benefits of blockchain technology is listed in Appendix I.

Specifically, the review studies classified the sample as per PPT model, including challenges in each category, and its

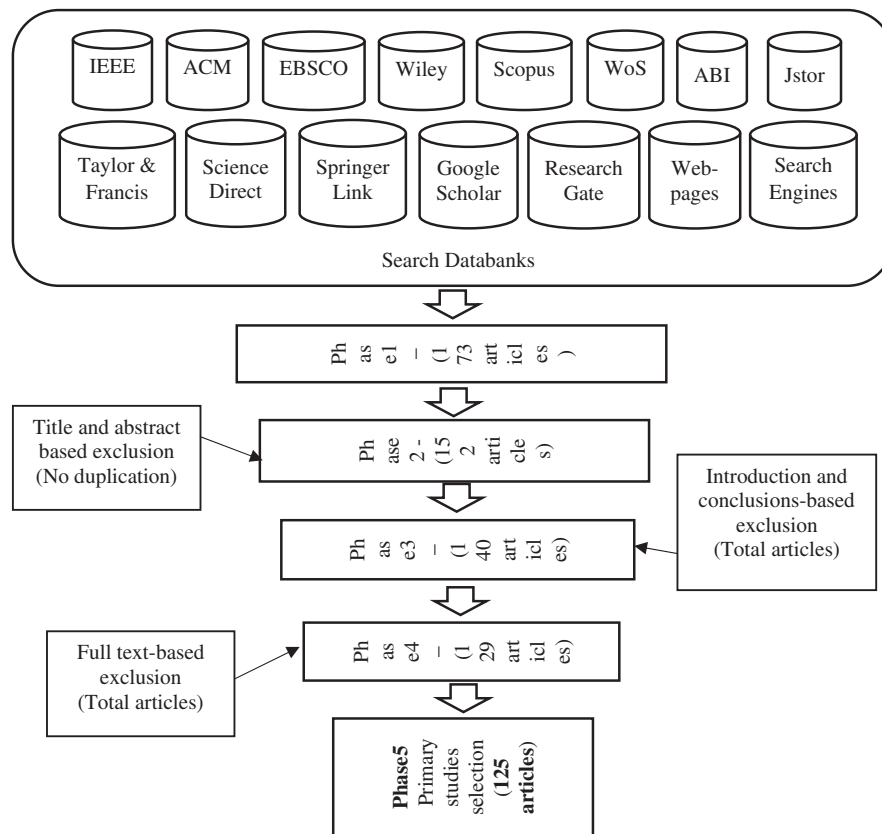

Figure 3. Tollgate approach for article selection.

benefits in terms of performance, including operational benefits concerning waste and safety. The review found several challenges in the people category, specifically, lack of skills, lack of motivation, lack of governance structure, and lack of collaboration. In the process category, our study finds challenges related to operational control in the food supply chain, operational standards, and best practices. The performance benefits listed in the category include traceability-related decisions and swift operations. From the technological perspective, the challenges listed by previous studies are initial cost of implementation, time concerns to complete the implementation, technological protocol, maturity of technology concerned with life cycle, and security risks. The performance benefits include sophistication offered through novel technologies, role of tools, and changes in approach.

3.2. Case interviews

To study the strategic challenges with respect to PPT, qualitative data were gathered through semi-structured interviews. As implementation of blockchain technologies is a niche and emerging area of research, we chose qualitative analysis as a methodology to address the research objectives of this study. Interview is a primary method of data collection in a qualitative study (Hatch 2002). The questions for the interview were prepared after identification of the relevant research gaps in the literature. Semi-structured interview questions were used to explore opportunities, impediments, and implementation issues for blockchain technology implementation in the food supply chain.

The participants included experts/stakeholders from the food industry who had an in-depth knowledge of tracking and tracing technologies and, to a certain extent, had a working knowledge of blockchain technology, or they were blockchain experts who had an awareness about the food sector. A semi-structured questionnaire was developed with twelve major questions. The questionnaire covered open pragmatic questions related to food and blockchain challenges, and opportunities in the four categories of technology, people, process, and performance. Blockchain technology is quite new, and only several companies have any idea about its potential and applications. Therefore, the convenience sampling technique was used to choose the companies. These companies were selected because of their proximity and accessibility (Bryman and Bell 2015) to two of the authors of this paper. Previous studies suggested selecting cases that have a potential to help and contribute to the research objectives (Subramanian, Chaudhuri, and Kayikci 2020). Hence, the convenience sampling method has been used in many of the recent studies (Batista et al. 2019; Jasimuddin and Naqshbandi 2019). Twelve semi-structured interviews were carried out in the leading technology and food chain companies over a period of several months from 01.04.2018 to 31.01.2019 in Turkey and India. Nine out of the twelve interviews were carried out in Turkey and the rest in India. In qualitative research, the sample size of 12 is considered to be sufficient for analysis, and qualitative studies have been published with sample sizes of even less than 10 (Krueger, Mellat Parast, and Adams 2014; Ramanathan et al. 2017; Kurpjuweit et al. 2019).

The respondents for the study from Turkey were from the business network of the first author. The companies were selected carefully on the basis of professionalism, knowledge, and experience. All associated companies were part of the food chain either as primary producer or technology provider since food blockchain technology was considered by big companies as a future scalable solution; hence, the interviews were carried out only with medium- or large-sized enterprises. The headquarters of all companies are located in Istanbul and Delhi. The semi-structured interviews were carried out through company visits, and each interview lasted almost three hours. The respondents who participated in this study were experienced professionals who were either expert in technology solutions with a good awareness of the food chain or vice versa or had in-depth knowledge of both. Seven experts were from the food sector and five were from the technology sector. The average length of experience of respondents who participated in the study was 16 years. In terms of level of education, the respondents possessed postgraduate degrees. The profiles of the respondents and the corresponding firms from Turkey involved in the interviews are shown in Table 2.

The potential respondents for the study from India were selected through a LinkedIn search. The search was made based on the keywords such as 'Food supply chain' and 'Blockchain'. Since blockchain technology is at a very nascent stage in India, very few professionals were engaged with the technology, and the search identified only a few. Finally, three people agreed to participate in the research and provide relevant input for this study. The average length of experience of the respondents was 25 years. Two of the respondents were postgraduates and one was a graduate in terms of education. Two respondents had medium exposure of blockchain technology, and one had low exposure. The profiles of respondents and the corresponding firms involved in the study are shown in Table 3.

During the interview, the experts were asked twelve questions as shown in Appendix II. The first question was associated with awareness of food safety scandals, such as the horsemeat scandal, salmonella outbreaks, and so forth. The other questions were asked in order to understand participants' perceptions and experiences of the ways in which, for example, they find the implementation challenge of blockchains, or companies' Information and Communication Technologies (ICT) requirements to adapt blockchain technology. All interviews were recorded.

4. Findings

A blockchain consortium brings like-minded organisations together and enables a new level of trust and transparency based on a single view of the truth; therefore, blockchain consortium are the widely accepted and appropriate models for use in business. From this aspect, further investigation is needed to understand if consortium blockchain technology might be the most suitable supply chain collaboration method in the food industry for food tracking and traceability, which enables a safer, more affordable, and more sustainable food

system. A successful integration of the blockchain requires the engagement of all participating organisations including farmers, suppliers, and retailers (Charlebois 2017). In order for goods to be traceable from farm to fork, all parties that handle the products should be linked to the blockchain. The key opportunities and impediments from the participants' responses are summarised in Table 4.

Overall, from Table 4, it is clear that opportunities and impediments are more in the people and technology perspectives. As expected, it is still too early to figure out the opportunities and impediments in the performance perspective. Interestingly, we did not see many issues in the process perspective. Measuring food loss, standardisation, and regulatory and legal acceptance are the immediate opportunities for people to consider in the process perspective of the application of blockchain technology in the food sector. Temperature management, validation, and standardisation are potential avenues for future researchers.

There is quite a high number of opportunities in the people perspective, of which redistributing surplus food, increasing customer loyalty, resisting corruption, reducing overall food price, and espousing anti-authoritarian protopia with a free decentralised society will lead multiple stakeholders to espouse blockchain technology in the future. However, if the community as a whole can focus on preparing competent manpower, creating a recognised consortium, and developing regulations to satisfy customer demand, then most of the people issues can be handled without any resistance to change.

On the technology front, there are a number of impediments since blockchain technology as a whole is new to the food chain. Hence, there are several technical issues that need to be resolved before it can be realised in practical terms. These include issues such as data capture, network maintenance, enterprise architecture model, interoperability between cold chain and blockchains, etc. Among all the above, it is interesting to note that the massive requirement of infrastructure and security will boost the usage of blockchains widely in the food sector. From the opportunity point of view, it is clear that there are massive benefits that outweigh the risk in the implementation.

5. Discussion and framework

Interaction of blockchain technology with people, process, and performance has several challenges. Typically, blockchain technology implementation has to learn from ERP implementation, which is an expensive solution, and it should be customised according to the needs of an enterprise. Customisation of ERP implementation is a major challenge in the food chain, as there are different types of products, and even the quality requirements for the same product (i.e. tomatoes) may differ. There are specific order processing modules for every product, which depend on the product requirements. Backward and forward lot traceability is another challenge.

An ICT system needs to establish a link between the blockchain technology and ERP systems to transfer the data to the inbound systems. For the application layer, both web

and mobile applications are required. A mining pool, consensus protocols, and hashing algorithms for the data access layer need to be arranged along with the smart contracts and cryptographic signatures. Smart contracts can automate quality control criteria.

The value achieved through integrating the blockchain technology with ERP systems comes not by creating and

importing new information into the distributed ledger but by drawing existing data from the enterprise systems and being able to tightly control with whom it is shared. Certainly, blockchain technology will be a complementary product for the ERP system.

The four perspectives from our analysis clearly indicate numerous impediment issues with respect to the people and

Figure 4. Publication year of the article.

Figure 5. Article classification as per source.

Figure 6. PPT aspect of articles.

technology perspectives. In general, the PPT model has been strategically used in different fields to enhance the quality of performance; in particular, there is evidence to suggest that data quality improves if there is proper blending between the three (Monterio 2016). Our findings based on the SLR and interviews illustrate the requirement of interaction of blockchain technology to enhance the relationship between the people and the process as well as between the process and the food supply chain performance. Overall, there is stronger evidence to suggest that balancing the relationship between the people and technology elements would significantly improve the performance. Similarly, blending the process and technology elements would minimise the errors and improve the performance of the food supply chain. The intervention of technology will have a stronger influence in the relationship between people's involvement and the process requirements as well as the relationship between the process requirements and the expected performance. Hence our research propositions for the study are as follows:

P1: Interaction of blockchain technology with the people and process relationship will improve the food supply chain performance.

P2: Interaction of blockchain technology with the process and performance relationship will improve the food supply chain performance.

The blockchain-based PPT model for food supply chain performance is shown in Figure 7. Further, this model is derived from data derived from several interviews conducted in emerging economies, such as Turkey and India, and needs to be tested using large-scale empirical data. Moreover, blockchain technology in the food industry has considerable potential to enhance traceability, transparency, and confidence, but substantial academic work is required, as there are many technical problems and obstacles. The technology transfers more business relationships into code (law). Industry public leaders and should embrace the blockchain technology as an opportunity, and it should be added to the digitalisation strategy currently affecting the entire food industry. Stringent regulations at both the national and the international level need to be implemented. The transparency, productivity, competitiveness, and sustainability of the food industry need to be enhanced. The technology will play

If we have data to analyse where food loss happens, we will have the ability to stop or decrease it dramatically <p>Table 4b: People issues in blockchain-enabled food supply chain</p> <ul style="list-style-type: none"> Redistribution of surplus food No manipulation, cryptology, reduction of transport, storage, handling cost, time and increase in quality Understand food loss and waste Customer loyalty, credibility and reduced costs Traceability and transparency Corruption resistance, traceability, authenticity, disintermediation, robustness, confidentiality Better bullwhip effect Openness culture anti-authoritarian; espousing protopian dreams of a free and decentralised society <p>Table 4c: Technology issues in Blockchain enabled food supply chain</p> <ul style="list-style-type: none"> Risk benefit will favour blockchains in terms of transparency and traceability Need-based analysis Database is used as a client-server network architecture Standalone blockchains for specific purposes ERP complementarity <p>Enterprise chain infrastructure</p>	<ul style="list-style-type: none"> Freezing temperature management in terms of excess standard and market values, spoiled milk and meat, salmonella-contaminated cheese, coliform bacteria in food or beverages Validation and standardisation research Skilled personnel are required Unique digital identifiers Standards Trustworthy consortium. Additional investment to work with other party Regulations and customer demand Validation, standards and regulation Intellectual rather than technological transformation, so takes time Legal and security integration is not clear Lack of common technology No central administration Interoperability Reliable data capture system, such as 5G technology Mining pool, consensus protocols, and hashing algorithms for the data access layer need to be arranged Technological capabilities (bandwidth etc.) are required for interconnections. An enterprise data architecture model is required Radio access network, transmission network, and IP backbone network are required For the application layer, both web and mobile applications are required ICT system needs to establish a link between blockchain and ERP systems to transfer the data to the inbound systems. ICT and cold chain should talk to each other. Customisation of ERP in a food chain is difficult; backward and forward lot traceability Capacity shortages and other difficulties can be tracked and managed in a timely fashion. Maintaining a blockchain network Blockchain implementations mostly done in C++ which is not a very friendly programming language for developers <p>Current bitcoin mining reward for adding a block to the chain is 12.5 + transaction charges (nearly between 13 to 14 Bitcoins). So technically, 12.5 bitcoins are being created out of thin air every 10 min.</p>
<p>Table 4d: Performance issues in blockchain-enabled food supply chain</p> <ul style="list-style-type: none"> Compliance at micro level delivery time, lot size, storage and transport conditions. 	<ul style="list-style-type: none"> Performance (latency, speed): Fresh preservation compliances

**Figure 7.** Blockchain-based PPT model for better food supply chain performance.

a major role in the food supply system, but right use cases (meat, dairy, fish, fruit, and vegetable products) need to be established. Nonetheless, the research should investigate how to generate evidence-based blockchain solutions for the entire food system.

6. Conclusion

A supply chain starts with a raw material and ends up with a product to be served to the customer. In between, there are many intermediaries. We usually trust the product and the company that produces the product or services. In the era of Industry 4.0, blockchain can eliminate the trust factor without anyone actually knowing the real situation. Blockchain technology enables trusted data storage with built-in privacy and management. The main purpose of using blockchain technology is security. Blockchain technology also improves supply chain transparency and chain of custody.

Our study answered the major research questions such as opportunities and impediments to implement blockchain technology in the food supply chain and the specific implementation issues at the micro level, such as people, process, technology, and performance. Typically, blockchain technology will ensure the non-manipulation of data, transparency, security, and collaboration among the stakeholders. The study contextualises PPT theory in an emerging economy to show the interaction effect of technology to strengthen the relationship between people, process, and performance. Specifically, the constructs include opportunities, impediments, and specific implementation issues of blockchain technology in the food supply chain from the actual experience of professionals in Turkey and India. The study can help managers in the food supply chain to leverage opportunities with the learning from emerging economy perspectives.

All the parties in a blockchain have a responsibility to distribute the right information. The retailer can monitor the current capacity of producers and be connected directly to make the new orders using the whole traceable system that makes it possible to collect the relevant information, like delivery time, lot size, and storage and transport conditions. Also, IoT devices need to be implemented throughout the food supply chain in order to capture comprehensive and consistent data across multiple parties and transmit the data to the blockchain. IoT devices can capture data for every parcel (pallet) of product, not just for a sample, while IoT answers questions of where, when, and what happened in the supply chain. The right application of IoT and blockchain technology can transform the supply chain, giving manufacturers and retailers the opportunity to succeed at both.

This study has several limitations, which can be addressed by future researchers. In this study, we have focussed on the food supply chain as a whole. However, the opportunities and impediments may change according to the type of food supply chain. This work is based upon the inputs from a few professionals in the food supply chain. The model proposed in the study needs to be validated using large-scale empirical evidence from both developed and developing countries. Future studies can also analyse the innovation diffusion of

blockchain technology in contextualised supply chains and advance the knowledge of innovation and technological advancement.

We are very thankful to Royal Academy of Engineering for supporting the authors to visit Turkey through DVFM project [DVFM 1718_1_54] titled 'Perishable food cold chain logistics in Turkey'.

Notes on contributors

Dr. Yasanur Kayikci is a Consultant and Assistant Professor of Logistics and Technology Management at the Turkish-German University in Istanbul, Turkey. Her research interests include new technologies and innovations (such as Industry 4.0, the Internet of Things, blockchain, and big data), information systems in logistics and supply chains, collaborative business models, food supply chains, sustainability and the circular economy.

Nachiappan Subramanian (Nachi) is the Professor of Operations and Logistics Management & Supply Chains at the University of Sussex UK. Nachi has 22 years of teaching experience in the UK, China, Australia and India. Nachi has published 100 journal articles in technology interventions in supply chain, sustainable supply chains and risk and resilience.

Dr. Manoj Dora has several years of experience in teaching, research and consultancy worldwide. He is the founder of 'Circular Food Forum' in the UK which brings together academic, industries and policy makers to facilitate dialogue and take forward research agenda. His areas of specializations are Sustainable Value Chain and Quality Management with a focus on Lean Six Sigma in the agro-food sector. Manoj's current research aims to map the circular pathway for food supply chain and its impact across the different stakeholders in the using 'lean thinking' principles.

Manjot Singh Bhatia is currently working as Assistant Professor at Jindal Global Business School, India. He holds Doctorate in Operations Management from Indian Institute of Management, Lucknow, India (AACSB accredited). His current research interests include sustainability, closed loop supply chain, and Industry 4.0. He has published in reputed Journals such as International Journal of

Production Research, Annals of Operations Research, Journal of Cleaner Production, etc.

Appendix I. Issues identified related to blockchain in FSC from SLR

People

Lack of skills:

- Lack of knowledge and engagement to blockchain technology and how to benefit from blockchain technology lead slower adoption (Ge et al. 2017; Ahlmann 2018).
- Lack of awareness (Ramachandran 2017; Hackius and Petersen 2017; Edmund 2018; WEF 2019b)
- Lack of impartial education (Kshetri and Voas 2018; WEF 2019b)

Lack of motivation:

- Lack of facilitation and encouragement of value chain partners (notably smallholder farming) does not provide genuine and precise information to blockchain ledger. Blockchain adoption of one farmer can exert normative pressure on the other members of FSC (Kshetri 2017).
- Enabling transparency in FSC through implementation of blockchain and other technologies requires considerable effort from all participants involved (Ahlmann 2018; Ramachandran 2017).

Lack of governance

- Lack of noneffective governance may lead the biggest obstacles for nonprivate, non-hierarchical ledgers (Ahlmann 2018). All blockchain powered FSC participants need to mutually agree on governance and consensus rules.

Lack of collaboration

- Participants needs to willingly share data and be open to collaborate (Crew 2020). Blockchain leads strategic cooperation in each level of FSC (Ahlmann 2018).

Anti-corruption and anti-food fraud:

- Blockchain provides opportunities such as transparency and fraud reduction, public safety, controlling financial waste or corruption and legal property improvement (Kshetri and Voas 2018; Tripoli and Schmidhuber 2018; Tiscini et al. 2020), internal external auditing, administrative and operations cost reduction, payment verifications and contract validity (Deloitte, 2016; Kshetri 2017) by allowing all members of an FSC community to monitor the activity of each other's credentialed staff (Casey and Wong 2017).

Benefit to agriculture finance:

- Blockchain solutions support farmers for transaction and payment side, crop insurance, microfinancing, improving farm production yields, delivering vaccines, or increasing access to education (Kim and Laskowski 2018a; Tripoli and Schmidhuber 2018; Maghfirah 2019)
- Creating economic identities for smallholder farmers (GSMA 2017)
- Faster and fairer payment to all members of FSC from farm to fork (Charlebois 2017; FAO 2019; Maghfirah 2019; WEF 2019b; Crew 2020)
- Disadvantaged groups (refugees, displaced persons) for payment and food supply (Godsiff 2016; Kshetri and Voas 2018)
- Farmland registry on blockchain and crowdfunding livestock (Deloitte, 2016)

Process

Lack of operational controls in FSC

- Lack of controlling time, temperature and tolerance effects in ensuring the food safety and food quality along the FSC processes (Tian 2016).
- Lack of operational capabilities (Deloitte 2019; Kamble, Gunasekaran, and Gawankar 2020)
- Lack of food integrity, security and transparency (Brewster 2017; van Hoek 2019)

Lack of standards in FSC

- Missing standards for the level of detail of traceability (Deloitte, 2017a; Behnke and Janssen, 2020)
- Lack of standardisation of internal processes in terms of critical traceability points and traceability data (Behnke and Janssen, 2020)
- Compliance with special quality requirements for food products (Behnke and Janssen, 2020)
- Standardisation of quality requirements among all participants in FSC (Galvez, Mejuto, and Simal-Gandara 2018; Behnke and Janssen, 2020)
- Low ICT penetration (Brewster 2017; Dujak and Sajter 2019; Duan et al. 2020)

Lack of best practices

- Lack of studies explaining or evaluating blockchain (Dobrovnik et al. 2018; Cottrill 2018; Cole, Stevenson, and Aitken 2019; Queiroz, Telles, and Bonilla 2019)
- Lack of empirical evidence (Cottrill 2018; Galvez, Mejuto, and Simal-Gandara 2018; Cole, Stevenson, and Aitken 2019; Creydt and Fischer 2019; Queiroz, Telles, and Bonilla 2019; Tönnissen and Teuteberg 2020)
- Lack of comparison with successful or unsuccessful technologies (Cole, Stevenson, and Aitken 2019)
- Stakeholder cooperation (Kamath 2018; Dobrovnik et al. 2018; Creydt and Fischer 2019; Duan et al. 2020)
- Blockchain's entry point to FSC is difficult to identify (Dobrovnik et al. 2018; Wang, Han, and Beynon-Davies 2019; Perera et al. 2020)
- Impact on current business models is unknown (Tönnissen and Teuteberg 2020)

Benefit to tracking and traceability

- Ensuring full transparency of FSC processes builds consumer trust for food products (i.e. organic food and fair-trade labelled products) as well as for food safety (i.e. protecting consumers from food borne diseases or health hazards) and increase ultimately confidence for the agri-food markets (Tian 2016; Tan et al. 2018; Azzi, Chamoun, and Sokhn 2019; Basnayake and Rajapakse 2019; Creydt and Fischer 2019; Kaur 2019; Morkunas, Paschen, and Boon 2019; Montecchi, Plangger, and Etter 2019)
- In-time detection of mistakes or errors coming from any part of FSC in case of occurring unsafety operating incidents (Kumar and Iyengar 2017; Sengupta, Singh, and Kim 2019; Tse et al. 2017)

Benefit to certification

- Quality or origin and food farmers certifications through blockchain (Papa 2017; Basnayake and Rajapakse 2019; Petersen, Hackius, and von See 2018).
- Cascading of certification and revocations (Brewster 2017; Sander, Semeijn, and Mahr 2018)

(continued)

Appendix I. Continued

People

- Quick response code embedded smart contracts identifies food product and farmers practically and cost effectively farm-to-fork assessment (Sander, Semeijn, and Mahr 2018; Basnayake and Rajapakse 2019)

Benefits to swift operations

- Blockchain technology in FSC for the products (i.e. canned tuna, poultry meat) validate supplies and upstream operations swiftly and efficiently (Bermeo-Almeida et al. 2018; Longo, Nicoletti, and Padovano 2019; Kittipanya-Ngam and Tan 2020; Perera et al. 2020)
- Proving authenticity against dishonest transaction (Tse et al. 2017; Creydt and Fischer 2019)
- effect food supply chain performance metrics (Kshetri 2018; Casino et al. 2019; Cole, Stevenson, and Aitken 2019; Gurtu and Johny 2019; Kamble, Gunasekaran, and Gawankar 2020)
- Automating commercial processes (i.e. recall) and trade promotions (Galvin 2017; DHL 2018; Longo, Nicoletti, and Padovano 2019; Wamba et al. 2020; Perera et al. 2020)

Technology

High cost and time concerns:

- There are high costs (i.e. investment) and data processing time for the integration of blockchain into the existing FSC traceability system. (Tian 2017; Lin and Liao 2017; Lin et al. 2017a; Pearson et al. 2019; Chen et al. 2020)
- The on-farm data (i.e. DNA of livestock animals) uploaded to blockchain-powered FSC can be expensive. (Gopi et al. 2019; Xiong et al. 2020)
- Transparent food production systems require rapid data exchange between stakeholders which leads to expedition of processes and transactions times (Astill et al. 2019).

Lack of standards

- Lacking uniformed technology standard makes adoption difficult (Zhao et al. 2019; Chen et al. 2020; Feng et al. 2020).
- The ownership of the maintenance responsibility and task (Antonucci et al. 2019; Deloitte 2017b)
- Need for the alignment on standards and technology infrastructure (WEF 2019a; Scuderi, Foti, and Timpanaro 2019)
- Required tamper-proof metadata infrastructure in order to adapt changing environments and regulations (Tian 2017)

Immaturity of technology:

- The speed of blockchain based transaction for storage and synchronisation, scalability in terms of throughput, latency, and capacity (Tian 2017), interoperability (Feng et al. 2020), architecture for security features, limited transactions (Burke 2019; Pearson et al. 2019) are major concerns to integrate blockchain with current FSC network (Yadav and Singh 2019; Zhao et al. 2019)
- Using blockchain and mobile apps runs on smartphones. The lack of access to mobile networks is the main constraint from farmer side to interrupt farm-to-fork data flow and food safety. Zambrano (2017)
- Blockchain adoption requires seamlessly integration with the existing database and legacy systems such as ERP, WMS, MES (Hollands et al. 2018; Perboli, Musso, and Rosano 2018; Baralla, Ibba, et al. 2019; Pearson et al. 2019; Martinez et al. 2019; Xiong et al. 2020)
- Blockchain requires more effective consensus mechanism to handle large number of nodes and resources stored in blockchain platform (Tsang et al. 2019; Zhao et al. 2019; Feng et al. 2020)
- The primary realisation of the infrastructure with different smart contracts and responsible (governmental or certified third party, etc.) (Antonucci et al. 2019; Baralla, Ibba, et al. 2019)
- Scalability obstacles in blockchain protocols (Lin et al. 2017a; Chen et al. 2020)
- Product complexity makes tracking difficult on blockchain platform (WEF 2019a)
- Associated technologies (i.e. sensing) for automated data transaction to blockchain need to be developed further (WEF 2019a; Pournader et al. 2020)

Security risk

- Cyber threats, cyber security risk, needs to improve base knowledge and technical assistance (Xu, Xu, and Li 2018; Antonucci et al. 2019; Shahid et al. 2020)
- Smart contracts have still security gaps and they are facing hacking incidents, because they are not mature enough (Shahid et al. 2020).

Benefit to tracking and traceability

- Trusted/authorised users verify the traceability and authenticity of the product at any point of FSC through blockchain adoption. (Tian 2016, Tian 2017, Yiannas 2018; Hammi et al. 2018; Ndraha et al. 2018), so that consumers can obtain the full information of the product in the whole FSC (Tian 2016; Kairos Future 2017; Carbone et al. 2018; Bordel et al. 2019; Chen et al. 2020; Liu, Yan, and Song 2020)
- Using smart contracts links up each process among food traceability stage (Lin et al. 2017a; Lin et al. 2017b Baralla, Ibba, et al. 2019; Pournader et al. 2020; Motta, Tekinerdogan, and Athanasiadis 2020)
- Allowing the verification of the integrity of data sworn by each authorised user in FSC (Baralla, Ibba, et al. 2019).
- Blockchain based quality assurance tracking enables same business rules and transaction data while reducing disputes among business partners, information asymmetries and consequently improving governance (Lucena et al. 2018; Perboli, Musso, and Rosano 2018; George et al. 2019)

Benefit to integration of new technologies

- Blockchain-based traceability system performs better with involving different technologies such as IoT (Christidis and Devetsikiotis, 2016; Caro et al. 2018; Hammi et al. 2018; Lin et al. 2018; Madumidha et al. 2019; Ivanov, Tsioulaniadis, and Schönberger 2019; Mistry et al. 2020), AI (Qian et al. 2020), unique identifiers such as RFID (Lin et al. 2017b ;Tian 2017; Ejaz and Anpalagan 2019; Gopi et al. 2019; Tsang et al. 2019) and QR code, NFC (Tsang et al. 2019), WSN, GPS (Chen et al. 2017), CPS and industrial information integration (Xu, Agbele, and Jiang 2019), fog/edge/cloud computing (Carbone et al. 2018), big data (Ndraha et al. 2018; Astill et al. 2019), 5G (Mistry et al. 2020) and food-sensing technologies (WEF 2019a) which have a great impact on the reduction of uncertainty, time consuming workflows and significant costs in FSC processes (Hollands et al. 2018; Zhao et al. 2019; Kamilaris, Font, and Prenafeta-Boldó 2019; Saberi et al. 2019; Lezoche et al. 2020; Detwiler 2020).
- Integrating blockchain technology with edge/cloud computing (SaaS) can achieve a higher-level knowledge sharing performance (i.e. automated recall, provenance assurance) through developing a distributed, sharing, standardised, and secured framework (ChainTrade 2017; ChainLink 2018; Zhao et al. 2019)
- Smart contracts automate the storage of product information related to the FSC (Te-food 2017; Mao et al. 2018a; Mao et al. 2018b; Baralla, Pinna, and Corrias 2019; Moudoud, Cherkaoui, and Khoukhi 2019).
- Use of innovative information technology-based solutions can be the safeguard to protect especially perishable food (Bechtsis et al. 2019; Mistry et al. 2020).

Appendix I. Continued

People

Benefit to integration of tools and approaches

- Using informal or semi-formal ontologies have greater impact for developing and operating blockchain to ensure better data standards, business practices and processes (Kim and Laskowski 2018b)
- FSC system with double chain architecture based on blockchain guarantees transparency, data safety, privacy of enterprise information as well as improves the credibility of service platform and overall efficiency of the system (Xie, Sun, and Luo 2017; Hollands et al. 2018; Leng et al. 2018; Mao et al. 2018a; Mao et al. 2018b; Moudoud, Cherkaoui, and Khoukhi 2019; Bumblauskas et al. 2020; Mezquita et al. 2020).
- An ICT e-agriculture system with blockchain infrastructure improves economic efficiencies, food safety with Quality of Experience (QoE) metrics based on food provenance and traceability (Carbone et al. 2018) and reduces uncertainty risk as while achieving sustainable agricultural development (Xie, Sun, and Luo 2017; Lin et al. 2017a; Lin et al. 2019).
- Remote monitoring and automation improve reliability and enable faster and efficient operations and scalability (Patil et al. 2018; Mistry et al. 2020)
- Using API (Pearson et al. 2019; Olsen, Borit, and Shaheen 2019), REST interfaces, NoSQL databases and Java-Script code (Bordel et al. 2019), encrypted biometrics (Xu, Agbele, and Jiang 2019) it is implemented a distributed solution to collect, sign and store trustworthy information about the food product flow

Appendix II. Questionnaire for case interviews

Questionnaire

Demographic data

1. Respondent position:
2. Total years of experience: Technology: Food:
3. Your exposure towards block chain: High/medium/low
4. ICT technology implementation experience in years:
5. Educational background

Semi structured interview questions

1. Are you aware of some of the food chain challenges? Say horse-meat scandal, chipotle chain scandal etc.
2. Can you please narrate the Blockchain implementation challenges?
3. You know digital ledger will bring in trust and accountability to what extent these prevent food loss.
4. Based on your view, how do you perceive Blockchain will reduce conflicts and improve collaboration in food chain?
5. Please narrate how Blockchain characteristic will reduce the food loss
6. Can you please let us know the advantage and disadvantages of ERP implementation in the food chain?
7. How will you compare ERP with Blockchain implementation, is it a substitutional or complimentary product?
8. You know food is subjected to several compliance such as safety risks, food security, and traceability. How Blockchain will comply with and reduce the role of intermediaries?
9. Can you please narrate the compatibility issues for companies to migrate towards Blockchain from the existing technologies?
10. What are the major motivators for companies to move towards Blockchain?
11. As you know there will be always a resistance to change to new technologies, in the case of Blockchain what type changes should happen at organizational micro and macro level.
12. Can you explain the essential ICT requirements to deploy a Blockchain solution from the technology provider infrastructure perspective?
